P5: WebAssembly Diversification for Malware evasion.

■ 1.6 Thesis outline

■ 2.1 WebAssembly

The W3C publicly announced the WebAssembly language in 2017 as the fourth scripting language supported in all major web browser vendors. Wasm is a binary instruction format for a stack-based virtual machine and was officially consolidated by the work of Haas et al. [?] in 2017. Wasm is designed to be fast, portable, self-contained and secure, and it promises to outperform JavaScript execution [?].

Since 2017, the adoption of Wasm keeps growing. For example; Adobe, announced a full online version of Photoshop¹ written in WebAssembly; game companies moved their development from JavaScript to Wasm like is the case of a full Minecraft version². Moreover, WebAssembly has been evolving outside web browsers since its first announcement. Some works demonstrated that using WebAssembly as an intermediate layer is better in terms of startup and memory usage than containerization and virtualization [? ?]. Consequently, in 2019, the Bytecode Alliance [?] proposed WebAssembly System Interface (WASI) [?]. WASI pioneered the execution of Wasm with a POSIX system interface protocol, making possible to execute Wasm directly in the operating system. Therefore, it standardizes the adoption of Wasm in heterogeneous platforms [?], making it suitable standalone and backend execution scenarios [? ?].

■ 2.1.2 WebAssembly's generation

WebAssembly programs are pre-compiled from source languages like C/C++, Rust, or Go, which means that it can benefit from the optimizations of the source language compiler. The resulting Wasm program is like a traditional shared library, containing instruction codes, symbols, and exported functions. A host environment is in charge of complementing the Wasm program, such as providing external functions required for execution within the host engine. For instance, functions for interacting with an HTML page's DOM are imported into the Wasm binary when invoked from JavaScript code.

TODO Expand on how we generate it

In Listing 2.1 and Listing 2.2, we illustrate a C program and its corresponding Wasm binary. The C function includes heap allocation, external function usage, and a function definition featuring a loop, conditional branching, function calls, and memory accesses. The Wasm code in Listing 2.2 displays the textual format of the generated Wasm (Wat).

```

// Some raw data
const int A[250];

// Imported function
int ftoi(float a);

int main() {
    for(int i = 0; i < 250; i++) {
        if (A[i] > 100)
            return A[i] + ftoi(12.54);
    }

    return A[0];
}

```

Listing 2.1: Example C program which includes heap allocation, external function usage, and a function definition featuring a loop, conditional branching, function calls, and memory accesses.

```

Listing 2.2: Wasm code for Listing 2.1. The example Wasm code illustrates the translation from C to Wasm in which several high-level language features are translated into multiple Wasm instructions.

■ 2.1.3 WebAssembly's binary format

The Wasm binary format is close to machine code and already optimized. Thus, its consuming process typically involves a straightforward one-to-one mapping. For example, a compiler might accelerate the compilation process by parallelizing the parsing process. The main reason behind this claim is that a Wasm binary is organized into a contiguous collection of sections. In Figure 2.1 we show the binary format of a Wasm section. A Wasm section starts with a 1-byte section ID, followed by an 8-byte section size, and concludes with the section content, which precisely matches the size indicated earlier.

Figure 2.1: Memory byte representation of a WebAssembly binary section, starting with a 1-byte section ID, followed by an 8-byte section size, and finally the section content.

A Wasm binary contains sections of 12 types, each with a specific semantic role and placement within the module. Each section is optional, where an omitted section is considered empty. In the following text, we summarize each one of the 12 types of Wasm sections, providing their name, ID, and purpose. In addition, some sections are annotated as comments in the Wasm code in Listing 2.2.

TODO Check if better with examples in each section

Custom Section (00) : Comprises two parts: the section name and arbitrary content. Primarily used for storing metadata, such as the compiler used to generate the binary. This type of section has no order constraints with other sections and is optional. Compilers usually skip this section when consuming a WebAssembly binary.

Type Section (01) : Contains the function signatures for functions declared or defined within the binary. It must occur only once in a binary. It can be empty.

Import Section (02) : Lists elements imported from the host, including functions, memories, globals, and tables. It must occur only once in a binary. It can be empty.

Function Section (03) : Details functions defined within the binary. It essentially maps Type section entries to Code section entries. It must occur only once in a binary. It can be empty.

Table Section (04) : Groups functions with identical signatures to control indirect calls. It must occur only once in a binary. It can be empty.

Memory Section (05) : Specifies the number and initial size of unmanaged linear memories. It must occur only once in a binary. It can be empty.

Global Section (06) : Defines global variables as managed memory for use and sharing between functions in the WebAssembly binary. It must occur only once in a binary. It can be empty.

Export Section (07) : Declares elements like functions, globals, memories, and tables for host engine access. The entry point of the WebAssembly binary is typically declared here. It must occur only once in a binary. It can be empty.

Start Section (08) : Designates a function to be called upon binary readiness, initializing the WebAssembly program state before executing any exported functions. It must occur only once in a binary. It can be empty.

Element Section (09) : Contains elements to initialize the binary tables. It must occur only once in a binary. It can be empty.

Code Section (10) : Contains the body of functions defined in the Function section. Each entry consists of local variables used and a list of instructions. It must occur only once in a binary. It can be empty.

Data Section (11) : Holds data for initializing unmanaged linear memory. Each entry specifies the offset and data to be placed in memory. It must occur only once in a binary. It can be empty.

Data Count Section (12) : Primarily used for validating the Data Section. If the segment count in the Data Section mismatches the Data Count, the binary is considered malformed. It must occur only once in a binary. It can be empty.

■ 2.1.4 WebAssembly's Runtime structure

TODO Reorder this text according with the wrules

The WebAssembly runtime structure is described in the WebAssembly specification by enunciating 10 key components: the Store, Stack, Locals, Module Instances, Function Instances, Table Instances, Memory Instances, Global Instances, Export Instances, and Import Instances. These components are particularly significant in maintaining the state of a WebAssembly program during its execution. In the following text, we provide a brief description of each runtime component. Notice that, the runtime structure is an abstraction that serves to validate Wasm consumers.

Store : The WebAssembly store represents the global state and is a collection of instances of functions, tables, memories, and globals. Each of these instances is uniquely identified by an address, which is usually represented as an i32 integer.

Module Instances : A module instance is a runtime representation of a loaded and initialized WebAssembly module. It contains the runtime representation of all the definitions within a module, including functions, tables, memories, and globals, as well as the module’s exports and imports.

Table instances : A table instance is a vector of function elements. WebAssembly tables are used to support indirect function calls. For example, it allows modeling dynamic calls of functions (through pointers) from languages such as C/C++, for which the Wasm’s compiler is in charge of populating the static table of functions.

Export Instances : Export instances represent the functions, tables, elements, globals or memories that are exported by a module.

Import Instances : Import instances represent the functions, tables, elements, globals or memories that are imported into a module from the host.

The Stack holds typed values and control frames, with control frames handling block instructions, loops, and function calls. Values inside the stack can be of the only static types allowed in Wasm 1.0, **i32** for 32 bits signed integer, **i64** for 64 bits signed integer, **f32** for 32 bits float and **f64** for 64 bits float. Therefore, abstract types, such as classes, objects, and arrays, are not natively supported. Instead, during compilation, such types are transformed into primitive types and stored in the linear memory.

Memory Instances represent the unmanaged linear memory of a WebAssembly program, consisting of a contiguous array of bytes. Memory instances are accessed with **i32** pointers (integer of 32 bits). Memory instances are usually bound in browser engines to 4Gb of size, and it is only shareable between the process that instantiates the WebAssembly module and the binary itself.

Global Instances : A global instance is a global variable with a value and a mutability flag, indicating whether the global can be modified or is immutable. Global variables are part of the managed data, i.e., their allocation and memory placement are managed by the host engine. Global variables are only accessible by their declaration index, and it is not possible to dynamically address them.

Locals : Locals are mutable variables that are local to a specific function invocation. As globals, locals are part of the managed data.

Note 1. *Along with this dissertation, as the work of Lehmann et al. [?], we refer to managed and unmanaged data to differentiate between the data that is managed by the host engine and the data that is managed by the WebAssembly program respectively.*

Function Instances : A function instance groups locals and a function body.

Locals are typed variables that are local to a specific function invocation. The function body is a sequence of instructions that are executed when the function is called. Each instruction either reads from the stack, writes to the stack, or modifies the control flow of the function. Recalling the example Wasm binary previously showed, the local variable declarations and typed instructions that are evaluated using the stack can be appreciated between Line 7 and Line 32 in Listing 2.2. Each instruction reads its operands from the stack and pushes back the result. In the case of Listing 2.2, the result value of the main function is the calculation of the last instruction, `i32.add` at result. As the listing shows, instructions are annotated with a numeric type.

■ 2.1.5 WebAssembly’s control flow

In WebAssembly, a defined function instructions are organized into blocks, with the function’s starting point serving as the root block. Unlike traditional assembly code, control flow structures in Wasm jump between block boundaries rather than arbitrary positions within the code. Each block might specify the required stack state before execution and the resulting stack state after its instructions have run. This stack state is used to validate the binary during compilation and to ensure that the stack is in a valid state before executing the block’s instructions. Blocks in Wasm are explicit, indicating, where they start and end. By design, each block cannot reference or execute code from outer blocks.

Control flow within a function is managed through three types of break instructions: unconditional break, conditional break, and table break. Importantly, each break instruction is limited to jumping to one of its enclosing blocks. Unlike standard blocks, where breaks jump to the end of the block, breaks within a loop block jump to the block’s beginning, effectively restarting the loop. To illustrate this, Listing 2.3 provides an example comparing a standard block and a loop block in a Wasm function.

```

block
  block
    br 1 ; Jump instructions
          ; are annotated with the
          ; depth of the block they
          ; jump to;
  end
end
...

loop
  ...
  br 0 ; first-order break;
  ...
end ; end instructions break
    ; the block and jump to next
    ; instruction;
...

```

Listing 2.3: Example of breaking a block and a loop in WebAssembly.

Each break instruction includes the depth of the enclosing block as an operand. This depth is used to identify the target block for the break instruction. For example, in the left-most part of the previously discussed listing, a break instruction with a depth of 1 would jump past two enclosing blocks. For the

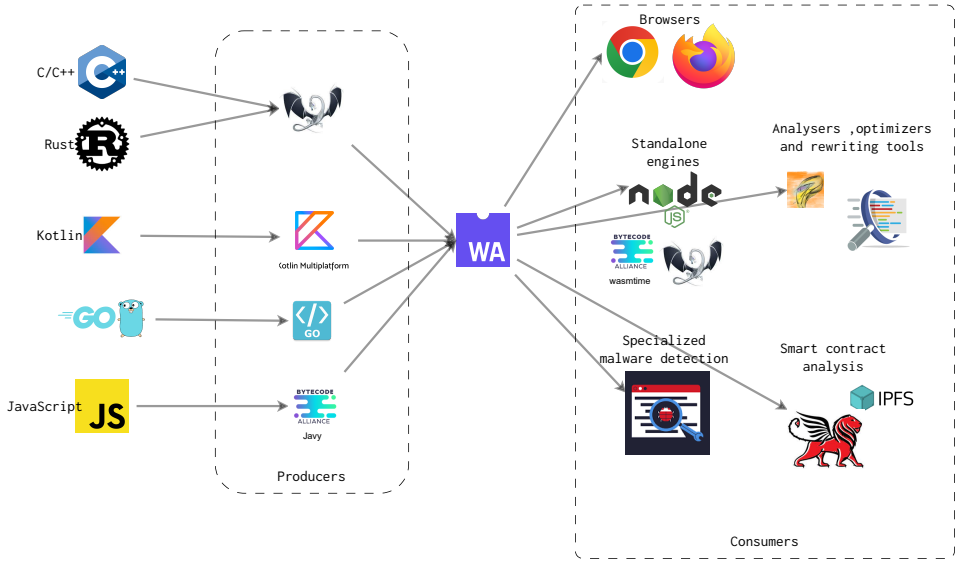

Figure 2.2: WebAssembly’s ecosystem landscape separated into producers and consumers. For the sake of simplicity we do not include each tool mentioned in this chapter.

purposes of this dissertation, we introduce a specific term to describe a particular kind of break within loops:

Definition 1. *Break instructions within loops that effectively jump to the loop’s beginning are termed first-order breaks.*

■ 2.1.6 WebAssembly’s Ecosystem

WebAssembly programs are designed for execution in host environments such as web browsers. Though the execution of a WebAssembly program might be considered its final lifecycle stage, the WebAssembly ecosystem is far from simplistic. It comprises multiple stakeholders and a rich array of tools that cater to various needs [?]. In Figure 2.2 we simplify the ecosystem landscape by separating it into producers, consumers and major stakeholders categories. In the subsequent text, we describe the WebAssembly ecosystem by separating it into stakeholders categories.

Producers , such as compilers, transform source code into WebAssembly binaries. For example, LLVM has offered WebAssembly as a backend option since its 7.1.0 release³, supporting a diverse set of frontend languages like C/C++,

³<https://github.com/llvm/llvm-project/releases/tag/llvmorg-7.1.0>

Rust, Go, and AssemblyScript⁴. In parallel developments, the KMM framework⁵ has incorporated WebAssembly as a compilation target, and the Javy approach⁶ focuses on encapsulating JavaScript code within isolated WebAssembly binaries. This is achieved by porting both the engine and the source code into a secure WebAssembly environment. Blazor also enables the compilation of C code into WebAssembly binaries for browser execution⁷. Regardless of the source language or framework, the resulting WebAssembly binary functions similar to a traditional shared library, replete with code instructions, symbols, and exported functions.

Consumers encompass tools that undertake the tasks of validating, analyzing, optimizing, transpiling to machine code, and executing WebAssembly binaries, e.g. browser clients. In the text that follows, we dissect them into specific categories and their respective domains of application. Notice that, while some tools are designed for a specific domain, others are more general-purpose and might encapsulate more than one task in the WebAssembly ecosystem. For example, this is the case of browsers and standalone engines, which in one way or the other perform each one of the previous tasks.

Browser engines like V8[?], SpiderMonkey[?], and Chakra[?] are at the forefront of executing WebAssembly binaries in browser clients. These engines leverage Just-In-Time (JIT) compilers to convert WebAssembly into machine code. This translation is typically a straightforward one-to-one mapping, given that WebAssembly is already an optimized format closely aligned with machine code, as previously discussed in Subsection 2.1.3. For example, V8 employs quick, rudimentary optimizations such as constant folding and dead code removal⁸.

Standalone engines WebAssembly’s applicability has transcended browser environments, largely due to the WebAssembly System Interface (WASI)[?]. WASI aims to standardize the interaction between host environments and WebAssembly modules, thereby facilitating portability of both bytecode and binaries across diverse platforms. It outlines a POSIX-like Application Binary Interface (ABI), which includes functionalities for filesystem access, network sockets, clocks, and random number generation, among others. Standalone engines such as WASM3[?], wasmtime[?], WAVM[?] and Sledge [?] have emerged to support WebAssembly and WASI. Similarly, Singh and colleagues [?] proposed a virtual machine for Wasm in Arduino based devices.

TODO Disect them into, JIT compilers and interpreters, ending with SWAM.

TODO Add the verifiable standalone engine here

⁴A subset of the TypeScript language

⁵<https://kotlinlang.org/docs/wasm-overview.html>

⁷<https://dotnet.microsoft.com/apps/aspnet/web-apps/blazor>

⁸This analysis was corroborated through discussions with the V8 development team and through empirical studies in one of our contributions[?]

TODO Locate WasmA [?]

Static and dynamic analysis, optimization and validation: Tools such as Wassail[?], Wasmati[?], and Wasp[?] utilize a range of strategies, including information flow control, code property graphs, and concolic execution, to identify vulnerabilities taking Wasm programs as input. Dynamic analysis counterparts like TaintAssembly[?], Wasabi[?], and Fuzzm[?] serve analogous functions.

TODO Binanryen **TODO** <https://soft.vub.ac.be/Publications/2023/vub-tr-soft-23-11.pdf>, https://dl.acm.org/doi/abs/10.1145/3510003.3510070?casa_token=hAlPiu9_oioAAAAA:Dskwqdm8c5-4e4W-8uU2CiENeyOXWoi6BHyTiZUgyxojSYWXBsaS7ERFeqGNKfaYIKIN8pnQ1 **TODO** Waff

TODO Add veriwasm **TODO** Wasmfuzzer

Specialized Malware Detection In niche areas like cryptomalware detection, tools like MineSweeper[?], MinerRay[?], and MINOS[?] utilize static analysis techniques. Conversely, dynamic analysis is the forte of tools like SEISMIC[?], RAPID[?], and OUTGuard[?].

Smart Contract Analysis In the field of smart contracts, static analysis tools like EvalHunter[?], WANA[?], and EOSAFE[?] are employed to unearth vulnerabilities in WebAssembly-based contracts. Dynamic analysis tools in this sphere include EOSFuzzer[?] and wasai[?].

Obfuscation, and binary rewriting tools [?] [?] **TODO** WASMixer, Wobfuscator

While many existing tools purport to offer self-correctness evaluations and exhaustive test suites, the WebAssembly ecosystem is still in its early stages. To emphasize this, a 2021 study by Hilbig et al.[?] found a mere 8,000 unique WebAssembly binaries globally. This pales in comparison to mature ecosystems like JavaScript and Python, which offer 1.5 million and 1.7 million packages on npm⁹ and PyPI¹⁰, respectively. This limited pool of WebAssembly binaries presents a unique challenge for machine learning-based analysis tools, which require large datasets for effective training. This issue is explicitly addressed in one of the contributions of this dissertation[?]. Additionally, the scarcity of WebAssembly programs exacerbates the problem of software monoculture, increasing the likelihood of consuming a compromised WebAssembly program[?]. Besides, the current size of the WebAssembly ecosystem offers a small testing environment for evaluating the capabilities of consumer tools. This dissertation aims to address these issues by introducing a comprehensive suite of tools. These tools are crafted to not only bolster the security of WebAssembly programs through Software Diversification but also to intensify the testing rigor for both producers and consumers in the ecosystem.

⁹<https://www.npmjs.com/>

¹⁰<https://pypi.org/>

■ 2.1.7 WebAssembly's Security

TODO Check the attack primitives defined by Lehmann. **TODO** Extend with more cases !

As we described, Wasm is deterministic and well-typed, follows a structured control flow and explicitly separates its linear memory model, global variables and the execution stack. This design is robust [?] and makes it easy for compilers and engines to sandbox the execution of Wasm binaries. Following the specification of Wasm for typing, memory, virtual stack and function calling, host environments should provide protection against data corruption, code injection, and return-oriented programming (ROP).

However, implementations in both browsers and standalone runtimes [?] are vulnerable. Genkin et al. demonstrated that Wasm could be used to exfiltrate data using cache timing-side channels [?]. Moreover, binaries itself can be vulnerable. The work of Lehmann et al. [?] proved that C/C++ source code vulnerabilities can propagate to Wasm such as overwriting constant data or manipulating the heap by overflowing the stack. Even though these vulnerabilities need a specific standard library implementation to be exploited, they make a call for better defenses for Wasm. Recently, Stiévenart and colleagues demonstrate that C/C++ source code vulnerabilities can be ported to Wasm [?]. Several proposals for extending Wasm in the current roadmap could address some existing vulnerabilities. For example, having multiple memories¹¹ could incorporate more than one memory, stack and global spaces, shrinking the attack surface. However, the implementation, adoption and settlement of the proposals are far from being a reality in all browser vendors¹².

¹²<https://webassembly.org/roadmap/>

■ 2.3 Exploiting Software Diversification

■ 2.3.2 Defensive Diversification

■ 2.3.3 Offensive Diversification

WebAssembly programs are produced ahead of time through a process that begins with the source code of the program and moves through a compiler, resulting in a WebAssembly program. Software Diversification can be achieved at any of these stages. Diversifying at the source code stage, however, is not practical due to the need of creating a distinct diversifier for each language compatible with WebAssembly. In contrast, focusing on the compiler stage presents a viable option, especially considering that 70% of WebAssembly binaries are created using LLVM-based compilers, as noted by Hilbig et al. [?]. Furthermore, implementing diversification at the WebAssembly program stage stands as the most generic strategy, applicable to any WebAssembly program in the wild. Therefore, this thesis focuses on the exploration of diversification strategies at the compiler and WebAssembly program stages, employing two main approaches: compiler-based and binary-based.

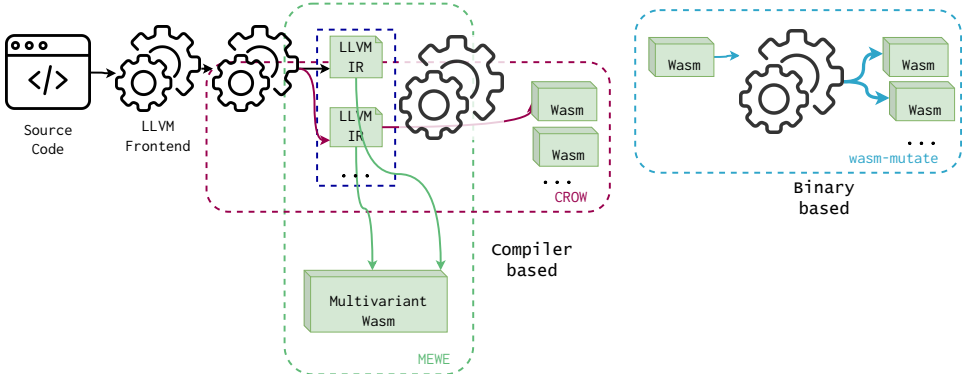

Figure 3.1: Approach landscape containing our three technical contributions: CROW squared in red, MEWE squared in green and WASM-MUTATE squared in blue. We annotate where our contributions, compiler-based and binary-based, stand in the landscape of generating WebAssembly programs.

Our compiler-based strategies are highlighted in red and green in Figure 3.1. This approach introduces a diversifier component in the LLVM pipeline, generating LLVM IR variants and producing artificial software diversity for Wasm. This strategy encompasses two tools: CROW [?], which creates Wasm program variants, and MEWE [?], which merges these variants to provide multivariant execution for Wasm. In contrast, the binary-based strategy, illustrated in blue in Figure 3.1, offers diversification for any WebAssembly program, removing the need for compiler tuning. WASM-MUTATE [?] generates a pool of WebAssembly program variants through rewriting rules upon an e-graph [?] data structure.

This dissertation contributes to the field of Software Diversification for WebAssembly, presenting three main technical contributions: CROW, MEWE, and WASM-MUTATE, dissected upon in the subsequent sections. Moreover, we compare our technical contributions between them. Furthermore, we outline the artifacts for our three technical contributions for the sake of open-research and reproducibility.

■ 3.1 CROW: Code Randomization of WebAssembly

This section details CROW [?], represented as the red squared tooling in Figure 3.1. CROW is designed to produce semantically equivalent Wasm variants from the output of an LLVM front-end, utilizing a custom Wasm LLVM backend.

Figure 3.2 illustrates CROW’s workflow in generating program variants, a process compound of two core stages: *exploration* and *combining*. During the *exploration* stage, CROW processes every instruction within each function of the LLVM input, creating a set of functionally equivalent code variants. This process ensures a rich pool of options for the subsequent stage. In the *combining* stage, these alternatives are assembled to form diverse LLVM IR variants, a task achieved through the exhaustive traversal of the power set of all potential combinations of code replacements. The final step involves the custom Wasm LLVM backend, which compiles the crafted LLVM IR variants into Wasm binaries.

■ 3.1.2 Variants’ generation

The primary component of CROW’s exploration process is its code replacement generation strategy. The diversifier implemented in CROW is based on the proposed superdiversifier methodology of Jacob et al. [?]. A superoptimizer focuses on *searching* for a new program that is faster or smaller than the original code while preserving its functionality. The concept of superoptimizing a program dates back to 1987, with the seminal work of Massalin [?] which proposes an exhaustive exploration of the solution space. The search space is defined by choosing a subset of the machine’s instruction set and generating combinations

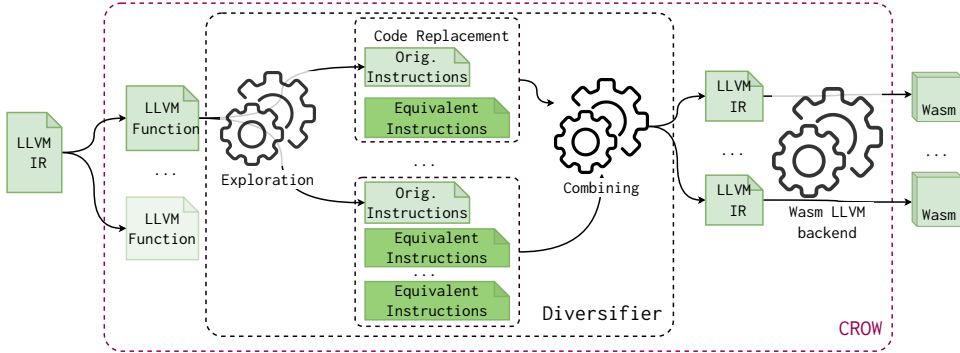

Figure 3.2: CROW components following the diagram in Figure 3.1. CROW takes LLVM IR to generate functionally equivalent code replacements. Then, CROW assembles program variants by combining them. Figure taken from [?].

of optimized programs, sorted by code size in ascending order. If any of these programs is found to perform the same function as the source program, the search halts. On the contrary, a superdiversifier keeps all intermediate search results despite their performance.

We build CROW upon an already existing superoptimizer for LLVM called Souper [?]. Yet, we modify it to keep all possible solutions in their searching algorithm. Souper builds a Data Flow Graph for each LLVM integer-returning instruction. Then, for each Data Flow Graph, Souper exhaustively builds all possible expressions from a subset of the LLVM IR language. Each syntactically correct expression in the search space is semantically checked versus the original with a theorem solver. Souper synthesizes the replacements in increasing size. Thus, the first found equivalent transformation is the optimal replacement result of the searching. CROW keeps more equivalent replacements during the searching by removing the halting criteria. Instead of the original halting conditions, CROW does not halt when it finds the first replacement. CROW continues the search until a timeout is reached or the replacements grow to a size larger than a predefined threshold.

Notice that the searching space increases exponentially with the size of the LLVM IR language subset. Thus, we prevent Souper from synthesizing instructions without correspondence in the Wasm backend. This decision reduces the searching space. For example, creating an expression having the **freeze** LLVM instructions will increase the searching space for instruction without a Wasm’s opcode in the end. Moreover, we disable the majority of the pruning strategies of Souper for the sake of more program variants. For example, Souper prevents the generation of commutative operations during the searching. On the contrary, CROW still uses such transformation as a strategy to generate program variants.

The last stage involves the custom Wasm LLVM backend, which generates the Wasm programs. For it, we have the premise of removing all built-in optimizations in the LLVM backend that could reverse Wasm variants. We disable all optimizations in the Wasm backend that could reverse the CROW transformations.

■ 3.1.3 Constant inferring

CROW, through using Souper adds a new transformation strategy that leads to more Wasm program variants, *constant inferring*. This means that Souper infers pieces of code as a single constant assignment. In particular, Souper focuses on variables that are used to control branches. After a *constant inferring*, the generated program is considerably different from the original program, being suitable for diversification.

Let us illustrate the case with an example. The Babbage problem code in Listing 3.1 is composed of a loop that stops when it discovers the smaller number that fits with the Babbage condition in Line 4.

```

1      int babbage() {
2          int current = 0,
3              square;
4          while ((square=current*current) %4
5              ↪ 1000000 != 269696) {
6              current++;
7          }
8          printf ("The number is %d\n",
9              ↪ current);
10         return 0 ;
11     }
```

Listing 3.1: Babbage problem.
Taken from [?].

```

1      int babbage() {
2          int current = 25264;
3
4
5
6
7
8          printf ("The number is %d\n", current);
9          return 0 ;
10     }
```

Listing 3.2:
Constant inferring transformation over
the original Babbage
problem in Listing 3.1. Taken from [?].

In theory, this value can also be inferred by unrolling the loop the correct number of times with the LLVM toolchain. However, standard LLVM tools cannot unroll the **while**-loop because the loop count is too large. The original Souper deals with this case, generating the program in Listing 3.2. It infers the value of **current** in Line 2 such that the Babbage condition is reached. Therefore, the condition in the loop will always be false. Then, the loop is dead code and is removed in the final compilation. The new program in Listing 3.2 is remarkably smaller and faster than the original code. Therefore, it offers differences both statically and at runtime¹

¹Notice that for the sake of illustration, we show both codes in C language, this process inside CROW is performed directly in LLVM IR.

■ 3.1.4 Combining replacements

When we retarget Souper, to create variants, we recombine all code replacements, including those for which a constant inferring was performed. This allows us to create variants that are also better than the original program in terms of size and performance. Most of the Artificial Software Diversification works generate variants that are as performant or iller than the original program. By using a superdiversifier, we could be able to generate variants that are better, in terms of performance, than the original program. This will give the option to developers to decide between performance and diversification without sacrificing the former.

On the other hand, when Souper finds a replacement, it is applied to all equal instructions in the original LLVM binary. In our implementation, we apply the transformations one by one. For example, if we find a replacement that is suitable for N difference places in the original program, we generate N different programs by applying the transformation in only one place at a time. Notice that this strategy provides a combinatorial explosion of program variants as soon as the number of replacements increases.

■ 3.1.5 CROW instantiation

Let us illustrate how CROW works with the example code in Listing 3.3. The `f` function calculates the value of $2 * x + x$ where `x` is the input for the function. CROW compiles this source code and generates the intermediate LLVM bytecode in the left most part of Listing 3.4. CROW potentially finds two integer returning instructions to look for variants, as the right-most part of Listing 3.4 shows.

```
1  int f(int x) {
2      return 2 * x + x;
3  }
```

Listing 3.3: C function that calculates the quantity $2x + x$.

<pre>define i32 @f(i32) { %2 = mul nsw i32 %0,2 %3 = add nsw i32 %0,%2 ret i32 %3 } define i32 @main() { %1 = tail call i32 @f(i32 10) ret i32 %1 }</pre>	<p>Replacement candidates for code_1</p> <pre>%2 = mul nsw i32 %0,2 %2 = add nsw i32 %0,%0 %2 = shl nsw i32 %0, 1:i32</pre>	<p>Replacement candidates for code_2</p> <pre>%3 = add nsw i32 %0,%2 %3 = mul nsw %0, 3:i32</pre>
---	---	---

Listing 3.4: LLVM's intermediate representation program, its extracted instructions and replacement candidates. Gray highlighted lines represent original code, green for code replacements.

<code>%2 = mul nsw i32 %0,2</code>	<code>%2 = mul nsw i32 %0,2</code>
<code>%3 = add nsw i32 %0,%2</code>	<code>%3 = mul nsw %0, 3:i32</code>
<code>%2 = add nsw i32 %0,%0</code>	<code>%2 = add nsw i32 %0,%0</code>
<code>%3 = add nsw i32 %0,%2</code>	<code>%3 = mul nsw %0, 3:i32</code>
<code>%2 = shl nsw i32 %0, 1:i32</code>	<code>%2 = shl nsw i32 %0, 1:i32</code>
<code>%3 = add nsw i32 %0,%2</code>	<code>%3 = mul nsw %0, 3:i32</code>

Listing 3.5: Candidate code replacements combination. Orange highlighted code illustrate replacement candidate overlapping.

CROW, detects `code_1` and `code_2` as the enclosing boxes in the left most part of Listing 3.4 shows. CROW synthesizes $2 + 1$ candidate code replacements for each code respectively as the green highlighted lines show in the right most parts of Listing 3.4. The baseline strategy of CROW is to generate variants out of all possible combinations of the candidate code replacements, *i.e.*, uses the power set of all candidate code replacements.

In the example, the power set is the cartesian product of the found candidate code replacements for each code block, including the original ones, as Listing 3.5 shows. The power set size results in 6 potential function variants. Yet, the generation stage would eventually generate 4 variants from the original program. CROW generated 4 statically different Wasm files, as Listing 3.6 illustrates. This gap between the potential and the actual number of variants is a consequence of the redundancy among the bitcode variants when composed into one. In other words, if the replaced code removes other code blocks, all possible combinations having it will be in the end the same program. In the example case, replacing `code_2` by `mul nsw %0, 3`, turns `code_1` into dead code, thus, later replacements generate the same program variants. The rightmost part of Listing 3.5 illustrates how for three different combinations, CROW produces the same variant. We call this phenomenon a *code replacement overlapping*.

<code>func \$f (param i32) (result i32)</code>	<code>func \$f (param i32) (result i32)</code>
<code> local.get 0</code>	<code> local.get 0</code>
<code> i32.const 2</code>	<code> i32.const 1</code>
<code> i32.mul</code>	<code> i32.shl</code>
<code> local.get 0</code>	<code> local.get 0</code>
<code> i32.add</code>	<code> i32.add</code>
<code>func \$f (param i32) (result i32)</code>	<code>func \$f (param i32) (result i32)</code>
<code> local.get 0</code>	<code> local.get 0</code>
<code> local.get 0</code>	<code> i32.const 3</code>
<code> i32.add</code>	<code> i32.mul</code>
<code> local.get 0</code>	
<code> i32.add</code>	

Listing 3.6: Wasm program variants generated from program Listing 3.3.

One might think that a reasonable heuristic could be implemented to avoid such overlapping cases. Instead, we have found it easier and faster to generate the variants with the combination of the replacement and check their uniqueness after the program variant is compiled. This prevents us from having an expensive checking for overlapping inside the CROW code. Still, this phenomenon calls for later optimizations in future works.

■ 3.2 MEWE: Multi-variant Execution for WebAssembly

This section describes MEWE [?]. MEWE synthesizes diversified function variants by using CROW. It then provides execution-path randomization in a Multivariant Execution (MVE). MEWE generates application-level multivariant binaries without changing the operating system or Wasm runtime. It creates an MVE by intermixing functions for which CROW generates variants, as illustrated by the green square in Figure 3.1. MEWE inlines function variants when appropriate, resulting in call stack diversification at runtime.

In Figure 3.3, we focus on MEWE, highlighted in green in Figure 3.1. MEWE takes the LLVM IR variants generated by CROW's diversifier. It then merges LLVM IR variants into a Wasm multivariant. In the figure, we highlight the two components of MEWE, *Multivariant Generation* and the *Mixer*. In the *Multivariant Generation* process, MEWE merges the LLVM IR variants created by CROW and creates an LLVM multivariant binary. The merging of the variants intermixes the calling of function variants, allowing the execution path randomization.

The Mixer augments the LLVM multivariant binary with a random generator. The random generator is needed to perform the execution-path randomization. Also, *The Mixer* fixes the entrypoint in the multivariant binary. Finally, using the same custom Wasm LLVM backend as CROW, MEWE generates a standalone multivariant Wasm binary. Once generated, the multivariant Wasm binary can be deployed to any Wasm engine.

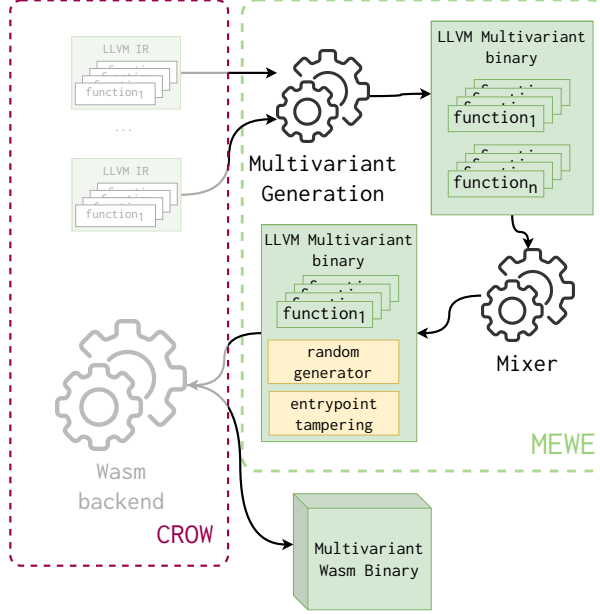

Figure 3.3: Overview of MEWE workflow. It takes as input an LLVM binary. It first generates a set of functionally equivalent variants for each function in the binary using CROW. Then, MEWE generates an LLVM multivariant binary composed of all the function variants. Finally, the Mixer includes the behavior in charge of selecting a variant when a function is invoked. Finally, the MEWE mixer composes the LLVM multivariant binary with a random number generation library and tampers the original application entrypoint. The final process produces a Wasm multivariant binary ready to be deployed. Figure partially taken from [?].

■ 3.2.2 Multivariant generation

The key component of MEWE consists of combining the variants into a single binary. The goal is to support execution-path randomization at runtime. The core idea is to introduce one dispatcher function per original function with variants. A dispatcher function is a synthetic function in charge of choosing a variant at random when the original function is called. With the introduction of the dispatcher function, MEWE turns the original call graph into a multivariant call graph, defined as follows.

In Figure 3.4, we show the original static call graph for an original program (top of the figure), as well as the multivariant call graph generated with MEWE (bottom of the figure). The gray nodes represent function variants, the green nodes function dispatchers, and the yellow nodes are the original functions. The

Figure 3.4: Example of two static call graphs. At the top, is the original call graph, and at the bottom, is the multivariant call graph, which includes nodes that represent function variants (in gray), dispatchers (in green), and original functions (in yellow). Figure taken from [?].

directed edges represent the possible calls. The original program includes three functions. MEWE generates 43 variants for the first function, none for the second, and three for the third. MEWE introduces two dispatcher nodes for the first and third functions. Each dispatcher is connected to the corresponding function variants to invoke one variant randomly at runtime.

```
define internal i32 @foo(i32 %0) {
  entry:
    %1 = call i32 @discriminate(i32 3)
    switch i32 %1, label %end [
      i32 0, label %case_43_
      i32 1, label %case_44_
    ]
  case_43_:
    %2 = call i32 @foo_43_(%0)
    ret i32 %2
  case_44_:
    %3 = <body of foo_44_ inlined>
    ret i32 %3
  end:
    %4 = call i32 @foo_original(%0)
    ret i32 %4
}
```

Listing 3.7: Dispatcher function embedded in the multivariant binary of the original function in the rightmost green node in Figure 3.4.

In Listing 3.7, we illustrate the LLVM construction for the function dispatcher

corresponding to the right most green node of Figure 3.4. It first calls the random generator, which returns a value used to invoke a specific function variant. We utilize a switch-case structure in the dispatchers to prevent indirect calls, which are vulnerable to speculative execution-based attacks [?]. The choice of a switch-case also avoids having multiple function definitions with the same signature, which could increase the attack surface in case the function signature is vulnerable [?]. This also allows MEWE to inline function variants inside the dispatcher instead of defining them again.

MEWE has four specific objectives: link the LLVM multivariant binary, inject a random generator, tamper the application's entrypoint, and merge all these components into a multivariant Wasm binary. We use the Rustc compiler² to orchestrate the mixing. For the random generator, we rely on WASI's specification [?] for the random behavior of the dispatchers. However, its exact implementation is dependent on the platform on which the binary is deployed. The Mixer component of MEWE creates a new entrypoint for the binary called *entrypoint tampering*. It wraps the dispatcher for the entrypoint variants as a new function for the final Wasm binary and is declared as the application entrypoint.

Contribution paper and artifact

MEWE is fully presented in Cabrera-Arteaga et al. "Multi-Variant Execution at the Edge" *Conference on Computer and Communications Security, MTD* <https://dl.acm.org/doi/abs/10.1145/3560828.3564007>

MEWE is also available as an open-source tool at <https://github.com/ASSERT-KTH/MEWE>

■ 3.3 WASM-MUTATE: Fast and Effective Binary for WebAssembly

In this section, we introduce our third technical contribution, WASM-MUTATE [?], a tool that generates functionally equivalent variants of a WebAssembly program input. Leveraging rewriting rules and e-graphs [?] for diversification space traversals, WASM-MUTATE synthesizes program variants by altering parts of the original binary. In Figure 3.1, we highlight WASM-MUTATE as the blue squared tooling for a visual representation.

Figure 3.5 illustrates the workflow of WASM-MUTATE, which initiates with a WebAssembly binary as its input. The first step involves parsing this binary to create suitable abstractions, e.g. an intermediate representation. Subsequently,

²<https://doc.rust-lang.org/rustc/what-is-rustc.html>

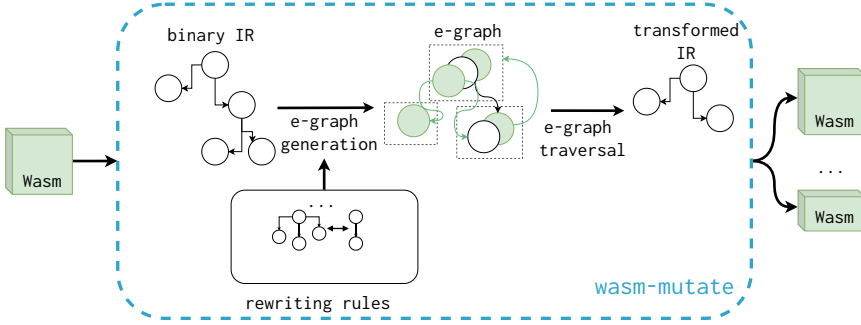

Figure 3.5: WASM-MUTATE high-level architecture. It generates semantically equivalent variants from a given WebAssembly binary input. Its central approach involves synthesizing these variants by substituting parts of the original binary using rewriting rules, boosted by diversification space traversals using e-graphs.

WASM-MUTATE utilizes predefined rewriting rules to construct an e-graph for the initial program, encapsulating all potential equivalent codes derived from the rewriting rules. Then, pieces of the original program are randomly substituted by the result of random e-graph traversals, resulting in a variant that maintains functional equivalence to the original binary. This assurance of semantic preservation is rooted in the inherent properties of the individual rewrite rules employed.

■ 3.3.2 WebAssembly Rewriting Rules

WASM-MUTATE incorporates a total of 135 rewriting rules, organized into categories referred to as meta-rules. The rewriting rules are conceived based on the seminal work of Sasnauskas et al. [?], extended to include a predicate to enforce the conditions for replacement. Each rule is articulated as a tuple, represented as (LHS, RHS, Cond), where: **LHS** identifies the segment of code targeted for replacement, **RHS** outlines the functionally equivalent substitute, and **Cond** defines the circumstances permitting the replacements. For example, in the case of WebAssembly binaries, the **Cond** predicate ensures that the replacement does not violate the type constraints. The following text details the seven meta-rules utilized in WASM-MUTATE.

Add type: WASM-MUTATE implements two rewrite rules for the Type Section of the input WebAssembly program. These rewriting rules create random function signatures, varying both, the number of parameters and the count of results. It ensures the consistency of the index of already defined types, even after the introduction of a new type. The following listing illustrates how WASM-MUTATE adds a new type definition based on this meta-rule.

```
LHS (module
  (type (;0;) (func (param i32) (result i64))))
```

```
RHS (module
  (type (;0;) (func (param i32) (result i64)))
  (type (;0;) (func (param i64 ... ) (result i32 ... ))))
```

Add function: WASM-MUTATE adds new random functions by mutating the code, type, and function sections. This process begins with the creation of a random type signature, followed by the formulation of a random function body that simply returns the default value corresponding to the result type. An illustration of this transformation is provided in the subsequent example.

```
LHS (module
  (type (;0;) (func (param i32 f32) (result i64))))
```

```
RHS (module
  (type (;0;) (func (param T) (result t)))
  (func (;0;) (type 0) (param T) (result t)
    t.const 0))
```

Debloat: WASM-MUTATE randomly eliminates dead parts of the input Wasm program, targeting specific elements such as *functions*, *types*, *custom sections*, *imports*, *tables*, *memories*, *globals*, *data segments*, and *elements* that are verifiably unused. For instance, the removal of a memory declaration needs the absence of any memory access operations within the binary code. WASM-MUTATE incorporates distinct mutators for each element type to facilitate this process. The following example showcases a function removal using this meta-rule.

```
LHS (module (import "" "" (func ))))
```

```
RHS (module )
```

Cond The removed function is not called, it is not exported, and it is not in the binary `table`.

Edit custom sections: WASM-MUTATE randomly changes either the content or the name of the custom section, a process illustrated in the subsequent example.

```

LHS (module
...
    (@custom "CS42" "zzz...")

RHS (module
...
    (@custom "... " "...")

```

If swapping: In WebAssembly, the if-construction is a compound of two paths: the consequence and the alternative. The determination of which execution path to follow depends on the branching condition evaluated just before the `if` instruction. Specifically, a value greater than 0 at the top of the execution stack triggers the execution of the consequence code, while any other outcome initiates the alternative code. The *if swapping* rewriting rule interchanges the consequence and alternative codes within the if-construction, effectively reversing the original paths defined by the condition.

To facilitate the swapping of an if-construction in WebAssembly, WASM-MUTATE introduces a negation of the value situated at the top of the stack immediately preceding the `if` instruction. The methodology behind this rewriting is demonstrated in the following example.

```

LHS (module
  (func ...) (
    condition C
    (if A else B end)
  )
)

RHS (module
  (func ...) (
    condition C
    i32.eqz
    (if B else A end)
  )
)

```

In this context, the consequence and alternative codes are labeled with the letters A and B, respectively, while the if-construction's condition is represented as C. To negate this condition, the `i32.eqz` instruction is incorporated into the RHS segment of the rewriting rule, functioning to compare the stack's top value with zero and, if true, pushing the value 1 onto the stack. In addition, WASM-MUTATE introduces a `nop` instruction to substitute for the absent code block, ensuring a seamless rewriting process.

Loop Unrolling: WASM-MUTATE randomly unrolls loops. To unroll a loop WASM-MUTATE first creates a new Wasm block, which contains a copy of its

body (unrolling) followed by the original loop. The copy of the loop body is itself a Wasm block. To maintain the original control flow functionality, the instructions inside the loop and their copied body need to be adjusted. To adjust the loop, WASM-MUTATE modifies the loop instructions that are first-order breaks, i.e., jumps that lead back to the loop's beginning and end (see section Subsection 2.1.4).

Inside the loop's body, there can be two types of first-order breaks: the first type which leads back to the loop's beginning, and the second type jumps, which leads to the loop's end. The second type is irrelevant for the unrolling process since the loop's end is not modified. To adjust first-order breaks, in the case of the copied body, they need to break the Wasm block that contains the loop body copy, making the execution of the program continue with the loop's original construction appended after it. In the case of the original loop, the first-order breaks need to interrupt the block that contains the loop body, making the execution of the program to continue as originally as the loop finishes. In concrete, their jumping indexes need to be incremented by one, going outside the loop-unrolling outer Wasm block. In the following example, we illustrate the unrolling of a loop.

```
LHS (module
  (func ...) (
    (loop A br_if 0 B end)
  )
)
```

```
RHS (module
  (func ...) (
    (block
      (block A' br_if 0 B' br 1 end)
      (loop A' br_if 0 B' end)
    end)
  )
)
```

In the LHS part of the rewriting rule, the loop showcases the first-order break. The loop concludes just before the `end` instruction if the break is not triggered. When WASM-MUTATE unrolls this loop, it undergoes a bifurcation of its instructions into two distinct groups, A and B. The RHS part of the illustration creates the two fresh Wasm blocks used for unrolling. Here, the outer block is a container for both the original and the duplicated loop body, while the inner entities, labeled A' and B', embody adjustments to the jump directives originally found in groups A and B. Moreover, the conclusion of the unrolled loop body copy is marked by the insertion of an unconditional branch `br 1`. This strategic placement guarantees that, in the absence of a continuation in the loop body, the operation exits the scope.

Peephole: This meta-rule focuses on the rewriting of instruction sequences

found within function bodies, representing the lowest level of rewriting. In WASM-MUTATE, we have devised 125 rewriting rules specifically for this category. WASM-MUTATE is structured to ensure the determinism of the instructions selected for replacement. Therefore, any rewriting rule inside the Peephole meta-rule avoids instructions that might induce undefined behavior, e.g., function calls. Consequently, the scope of this meta-rule is confined to modifications in stack and memory operations, preserving the original functionality of the control frame labels.

The peephole category rewriting rules are meticulously designed and manually verified. An instance of a rewriting rule in this category can be appreciated below:

LHS (x)

RHS (x i32.or x)

Cond x is i32 type

The previous rewriting rule example implies that the LHS 'x' is to be replaced by an idempotent bitwise `i32.or` operation with itself, as soon as x, which can be any subexpression, leaves a value of type `i32` in the execution stack.

■ 3.3.3 Extending peephole meta-rules with custom operators

As illustrated in Figure 3.5, the initial step in the process involves parsing an input WebAssembly program, generating an intermediate representation. This step facilitates the transition of the WebAssembly program to the next stages of WASM-MUTATE. This representation extends the textual Wat format. We augment it with custom operator instructions to enhance the transformation capabilities of WASM-MUTATE.

Custom operator instructions form part of the lowest level of transformation we provide in WASM-MUTATE, the Peephole meta-rule. These custom operator instructions are designed to bolster WASM-MUTATE by utilizing well-established code diversification techniques through rewriting rules. WASM-MUTATE includes four custom operator instructions in its intermediate representation of Wasm programs. In the following text, we describe each one of them. We also show concrete rewriting rules in the Peephole meta-rule that use them.

container : it acts as a holder for multiple instructions, enabling transformations without altering the program's semantics. Below, we demonstrate a rewriting rule that leverages it to insert `nop` instructions into the any WebAssembly program place, a well-known low-level diversification strategy [?]:

LHS `x`

RHS `(container (x nop))`

The instruction `x` (it can be a complete subexpression), can be substituted with `container (x nop)`. Thus, when converting back the intermediate representation to Wasm, a `nop` opcode is appended to the original instruction.

useglobal: this operator is used in a rewriting rule that substitutes its operand with the setting and retrieval actions involving a newly created global variable. In the following listing, we illustrate such a rewriting rule.

LHS `x`

RHS `(useglobal x)`

This rewriting rule is meant to stress the managed memory through random access to global variables.

unfold: this operator, working with a constant numeric operand, statically generates two numbers whose sum equals the constant, followed by the addition of operations for these numbers.

LHS `(i32.const x)`

RHS `(unfold x)`

rand: this operator injects random constant numbers in any place of the program. One of the rewriting rules using this operator is shown below.

LHS `x`

RHS `(container (x drop (rand)))`

In this rewriting rule, a subexpression is replaced by a container for which operands are the subexpression itself and the pushing of a random value into the execution stack, to be removed after with a `drop` instruction.

In practice, custom operators are only part of the rewriting rules of WASM-MUTATE. This means that, when converting Wasm to the intermediate representation no custom operator is generated. When converting back to the WebAssembly binary format from the intermediate representation, custom instructions are meticulously handled to retain the original functionality of the WebAssembly program. For example, the `container` custom operator is removed while its operands are encoded back to Wasm in their corresponding opcodes.

■ 3.3.4 E-graphs

We developed WASM-MUTATE leveraging e-graphs, a specific graph data structure for representing rewriting rules [?]. Within an e-graph, there exist two distinct node types: e-nodes and e-classes. The former encapsulates either an operator or an operand present in the rewriting rule, while the latter groups e-nodes into equivalence classes, essentially serving as a composite virtual node that contains a collection of e-nodes. Consequently, each e-class contains at least one e-node. e-nodes have edges delineating the operator-operand equivalence relations between e-classes.

In the context of WASM-MUTATE, the e-graph is constructed from a WebAssembly program. This entails the transformation of each distinct expression, operator, and operand into e-nodes. A primer e-graph is built from the original program. This initial e-graph is subsequently augmented with e-nodes and e-classes derived from each one of the rewriting rules.

Let us illustrate the e-graph construction with a program that consists of a single instruction that returns an integer constant, denoted as `i64.const 0`. Besides, assume a single rewriting rule defined as `(x, x i64.or x, x returns type i64)`. In Figure 3.6 we visualize how the e-graph is built out of the program and rewriting rule.

Building the e-graph begins with the incorporation of the solitary program instruction, `i64.const 0`, as an e-node ①. Then, we derive additional e-nodes from the rewriting rule ②. This involves introducing a fresh e-node labeled `i64.or` and establishing edges leading to the `x` e-node. Since there is no extra condition in which the operator-operand relation is valid, `x` represents any e-class in the e-graph. Thus, the equivalence by merging the two e-nodes is affirmed, thus forming a unified e-class ③. Finally, we successfully construct an e-graph that encapsulates the relationships and equivalences dictated by the initial program and the rewriting rule ④, setting the stage for further analyses and transformations based on this structured representation.

■ 3.3.5 Random e-graph traversal for variants generation

Willsey et al. demonstrated the potential for high flexibility in extracting code fragments from e-graphs, a process that can be recursively orchestrated through a cost function applied to e-nodes and their respective operands. This methodology ensures the semantic equivalence of the derived code [?]. For instance, e-graphs solve the problem of providing the best code out of several optimization rules [?]. To extract the "optimal" code from an e-graph, one might commence the extraction at a specific e-node, subsequently selecting the AST with the minimal size from the available options within the corresponding e-class's operands. In omitting the cost function from the extraction strategy leads us to a significant property: *any path navigated through the e-graph yields a semantically equivalent code variant.*

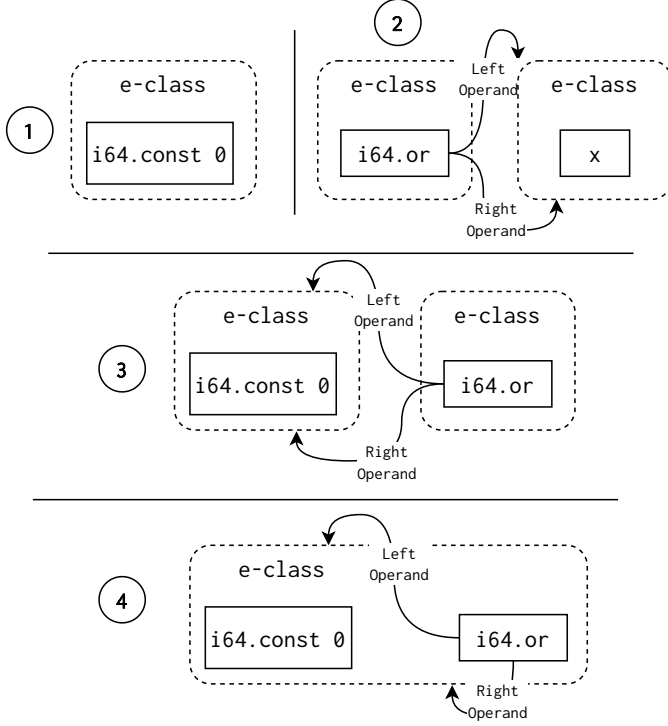

Figure 3.6: e-graph construction for idempotent bitwise-or rewriting rule and a single instruction Wasm program. Solid lines represent operand-operator relations, and dashed lines represent equivalent class inclusion.

The previously mentioned property is exploited in Figure 3.6, showcasing the feasibility of crafting an endless series of "or" operations. We exploit such property to generate diverse WebAssembly variants. We propose and implement an algorithm that facilitates the random traversal of an e-graph to yield semantically equivalent program variants, as detailed in Algorithm 1. This algorithm operates by taking an e-graph, an e-class node (starting with the root's e-class), and a parameter specifying the maximum extraction depth of the expression, to prevent infinite recursion. Within the algorithm, a random e-node is chosen from the e-class (as seen in lines 5 and 6), setting the stage for a recursive continuation with the offspring of the selected e-node (refer to line 8). Once the depth parameter reaches zero, the algorithm extracts the most concise expression available within the current e-class (line 3). Following this, the subexpressions are built (line 10) for each child node, culminating in the return of the complete expression (line 11).

Algorithm 1 e-graph traversal algorithm taken from [?].

```

1: procedure TRAVERSE(egraph, eclass, depth)
2:   if depth = 0 then
3:     return smallest_tree_from(egraph, eclass)
4:   else
5:     nodes  $\leftarrow$  egraph[eclass]
6:     node  $\leftarrow$  random_choice(nodes)
7:     expr  $\leftarrow$  (node, operands = [])
8:     for each child  $\in$  node.children do
9:       subexpr  $\leftarrow$  TRAVERSE(egraph, child, depth - 1)
10:      expr.operands  $\leftarrow$  expr.operands  $\cup$  {subexpr}
11:   return expr

```

■ 3.3.6 WASM-MUTATE instantiation

Let us illustrate how WASM-MUTATE generates variant programs by using the before enunciated algorithm. Here, we use Algorithm 1 with a maximum depth of 1. In Listing 3.8 a hypothetical original Wasm binary is illustrated. In this context, a potential user has set two pivotal rewriting rules: (`x`, `container (x nop),`) and (`x`, `x i32.add 0, x instanceof i32`). The initial rule, which has been previously discussed in Subsection 3.3.3, grants the ability to append a `nop` instruction to any subexpression within the program. Conversely, the latter rule articulates the equivalence of augmenting any numeric value by zero.

```

(module
  (type (;0;) (func (param i32 f32) (result i64)))
  (func (;0;) (type 0) (param i32 f32) (result i64)
    i64.const 1)
)

```

Listing 3.8: Wasm function.

```

(module
  (type (;0;) (func (param i32 f32) (result i64)))
  (func (;0;) (type 0) (param i32 f32) (result i64)
    (i64.add (
      i64.const 0
      i64.const 1
      nop
    ))
  )
)

```

Listing 3.9: Random peephole mutation using egraph traversal for Listing 3.8 over e-graph Figure 3.7. The textual format is folded for better understanding.

Leveraging the code presented in Listing 3.8 alongside the defined rewriting

Figure 3.7: e-graph built for rewriting the first instruction of Listing 3.8.

rules, we build the e-graph, simplified in Figure 3.7. In the figure, we highlight various stages of Algorithm 1 in the context of the scenario previously described. The algorithm initiates at the e-class with the instruction `i64.const 1`, as seen in Listing 3.8. At ②, it randomly selects an equivalent node within the e-class, in this instance taking the `i64.add` node, resulting: `expr = i64.add 1 r`. As the traversal advances, it follows on the left operand of the previously chosen node, settling on the `i64.const 0` node within the same e-class ③. Then, the right operand of the `i64.add` node is chosen, selecting the `container` ④ operator yielding: `expr = i64.or (i64.const 0 container (r nop))`. The algorithm chooses the right operand of the `container` ⑤, which correlates to the initial instruction e-node highlighted in ⑥, culminating in the final expression: `expr = i64.or (i64.const 0 container(i64.const 1 nop)) i64.const 1`. As we proceed to the encoding phases, the `container` operator is ignored as a real Wasm instruction, finally resulting in the program in Listing 3.9.

Notice that, within the e-graph showcased in Figure 3.7, the `container` node maintains equivalence across all e-classes. Consequently, increasing the depth parameter in Algorithm 1 would potentially escalate the number of viable variants infinitely.

Contribution paper and artifact

WASM-MUTATE is fully presented in Cabrera-Arteaga et al. "WASM-MUTATE: Fast and Effective Binary Diversification for WebAssembly" <https://arxiv.org/pdf/2309.07638.pdf>.

WASM-MUTATE is available at <https://github.com/bytecodealliance/wasm-tools/tree/main/crates/wasm-mutate> as a contribution to the bytecodealliance organization [?].

■ 3.4 Comparing CROW, MEWE, and WASM-MUTATE

In this section, we discuss the main differences between CROW, MEWE, and WASM-MUTATE. We discuss the main differences between CROW, MEWE, and WASM-MUTATE according to three main dimensions: 1) the technology and approach of each one, 2) the strength of the generated variants, and, 3) the security guarantees of the variants generated by each tool. We select these three dimensions because they lead the implementation of our tools.

■ 3.4.2 Technology and approach

CROW is a compiler-based strategy, needing access to the source code or its LLVM IR representation to work. Its core is a Satisfiability Modulo Theories (SMT) solver, ensuring the functional equivalence of the generated variants. This approach lays the groundwork for a universal LLVM superdiversifier, potentially extending its applications and adaptability to other technologies. MEWE extends the capabilities of CROW, utilizing the same underlying technology to create program variants. It goes a step further by packaging the LLVM IR variants into a Wasm multivariant, providing MVE through execution path randomization.

On the other hand, WASM-MUTATE is a semi-automated, binary-based tool, centralizing its core around e-graph traversals. This approach facilitates the creation of a pool of WebAssembly program variants through the meticulous application of rewriting rules on an e-graph data structure. This method removes the need for compiler adjustments, offering compatibility with any existing WebAssembly binary. Moreover, it highlights how extending intermediate representations could establish a general framework for binary rewriting in WebAssembly.

■ 3.4.3 Strength of the generated variants

CROW and MEWE use enumerative synthesis and verify semantic equivalence through SMT solvers. This approach not only has the potential to exceed

handcrafted optimizations but also ensures that the transformations are preserved. In other words, the transformations generated out of CROW and MEWE are virtually irreversible, even following compiler optimizations. This is particularly remarkable in the case of *constant inferring* transformations (see Subsection 3.1.3). While CROW and MEWE do not require any extra input but the program to diversify, the speed of variant generation is intrinsically linked to the SMT solvers' efficiency, known to be slow. Besides, their variants' generation capabilities are limited by the *overlapping* phenomenon discussed in Subsection 3.1.5.

On the other hand, WASM-MUTATE adopts a semi-automatic approach, requiring users to set the rewriting rules. Thus, the responsibility of ensuring functional equivalence is transferred to the rule creation process. This tool offers a significant advantage over CROW and MEWE as it permits transformations in any section of a Wasm program, not just the code section. Moreover, it leverages a virtually cost-free e-graph traversal process, avoiding, as a direct consequence, the *overlapping* issue seen in CROW and MEWE, as detailed in Subsection 3.1.5. In addition, since WASM-MUTATE operates at the binary level, it can modify functions incorporated by the WebAssembly producer itself. For example, this is the case of the *wasm32-wasi* architecture. While the original program might have a few lines of code, the underlying compiler might inject more functions to support the *wasm32-wasi* architecture. Thus, augmenting the diversification space available to WASM-MUTATE. Moreover, WASM-MUTATE outperforms CROW and MEWE capabilities in terms of the number of generated variants. Yet, the changes made by WASM-MUTATE might not be as preserved as the ones generated by CROW and MEWE. Thus, the variants generated by WASM-MUTATE might be more susceptible of being reversed, e.g. by further optimization passes.

Remarkably, CROW, MEWE, and WASM-MUTATE generate variants that potentially improve the original program's runtime performance, demystifying that software diversification inherently compromises performance.

■ 3.4.4 Security guarantees

CROW and MEWE generate distinct and highly preserved code variants. This means that these variants, each with unique WebAssembly codes, maintain their distinctiveness even after JIT compilers translate them into machine codes (see Subsection 2.1.6). WASM-MUTATE, while offering slightly reduced preservation in its generated variants compared to CROW and MEWE, still maintains the same security guarantees excepting the multivariant cases. Its ability to produce a greater number of variants can offset this preservation shortfall. The preservation feature significantly reduces the impact of side-channel attacks that exploit specific machine code instructions, e.g., port contention [?].

Furthermore, CROW and MEWE enhance security against timing-based attacks by creating variants that exhibit a wide range of execution times.

This strategy is especially prominent in MEWE’s approach, which develops multivariants functioning on randomizing execution paths, thereby thwarting attempts at timing-based inference attacks. Consequently, attackers might find it exceedingly difficult to identify a specific variant through time profiling of a MEWE multivariant (see Subsection 4.2.2 for the use case impact). Adding another layer benefit, the integration of diverse variants into multivariants can potentially disrupt dynamic analysis tools such as symbolic executors [?]. Concretely, different control flows through a random discriminator, exponentially increase the number of possible execution paths, making multivariant binaries virtually unexplorable.

An advantage of WASM-MUTATE, compared to CROW and MEWE, is its capacity to transform non-code sections without impacting the runtime behavior of the original variant, a strategy that effectively shields against static binary analysis, including malware detection based on signature sets [?]. For instance, it can modify the type section of a WebAssembly program, a section typically utilized only for function signature validation during compilation and validation processes by the host engine. This thwarts compiler identification techniques, such as fingerprinting. Besides, it can be used for masquerading as a different compilation source. Thus, reducing the fingerprinting surface available to attackers.

CROW, MEWE, and WASM-MUTATE can alter the original program structure, either by eliminating dead code or by introducing additional elements. From a static perspective, such alterations serve to reduce potential attack surfaces, thereby impeding signature-based identification. Yet, modifying the layout of a WebAssembly program inherently affects its managed memory during runtime, a segment not overseen by the WebAssembly program itself (see section ?? for a detailed discussion on unmanaged memory). This aspect is especially important for CROW and MEWE, given that they do not directly address the WebAssembly memory model. Significantly, CROW and MEWE considerably alter the managed memory by modifying the layout of the WebAssembly program. For example, the *constant inferring* transformations significantly alter the layout of program variants, affecting unmanaged memory elements such as the returning address of a function.

Furthermore, WASM-MUTATE not only affects managed memory through changes in the WebAssembly program layout. It also adds rewriting rules to transform unmanaged memory instructions, e.g. the rewriting rule involving the `useglobal` custom operator previously discussed in Subsection 3.3.3. Memory alterations, either to the unmanaged or managed memories, have substantial security implications. For instance, they can counteract attacks by eliminating potential jump points that facilitate malicious activities within the binary, a preventive measure highlighted by Narayan et al. [?].

■ 3.5 Conclusions

In this chapter, we discuss the technical specifics underlying our primary technical contributions. We elucidate the mechanisms through which CROW generates program variants. Following this, we outline the conceptual framework for a universal LLVM superdiversifier, laying a foundation for broader applicability and versatility. Subsequently, we discuss MEWE, offering a detailed examination of its role in forging MVE for WebAssembly. We also explore the details of WASM-MUTATE, highlighting its pioneering utilization of an e-graph traversal algorithm to spawn Wasm program variants. Remarkably, we undertake a comparative analysis of the three tools, delineating their respective benefits and limitations, alongside the potential security assurances they provide upon the program variants derived from them.

In ??, we present four use cases that support the exploitation of these tools. ?? serves to bridge theory with practice, showcasing the tangible impacts and benefits realized through the deployment of CROW, MEWE, and WASM-MUTATE.

■ 4.1 Offensive Software Diversification

- 4.1.2 **Use case 1:** Automatic testing and fuzzing of WebAssembly consumers

TODO We explain the CVE. Make the explanation around "indirect memory diversification"

- 4.1.3 **Use case 2:** WebAssembly malware evasion

TODO The malware evasion paper

■ 4.2 Defensive Software Diversification

- 4.2.2 **Use case 3:** Multivariant execution at the Edge

TODO Disturbing of execution time. Go around the web timing attacks. <https://arxiv.org/pdf/2210.10523.pdf> Attack model for MEWE.

- 4.2.3 **Use case 4:** Speculative Side-channel protection

In concrete, distributing the unmodified binary to 100 machines would, essentially, creates 100 homogeneously vulnerable machines. However, let us illustrate the case with a different approach: each time the binary is replicated onto a different machine, we distribute a unique variant instead of the original binary. If we disseminate a unique variant, with X stacked transformations, to each machine, every system would run a distinct Wasm binary. Based on our findings, even when some binaries are still vulnerable, we can confidently say that if 100 variants of a vulnerable program, each furnished with X stacked transformations, are distributed, the impact of any potential attack is considerably mitigated. While it's true that some variants may retain their original vulnerabilities, not all

of them do. This significantly enhances overall security. Further reinforcing this point, let's consider the case of `btb_leakage`. In this scenario, a suite of 100 variants, each featuring at least 200 stacked transformations, ensures full protection against potential threats, effectively securing the entire infrastructure. Moreover, considering the results for the `ret2spec` attack, this property holds for the whole population of generated variants, despite the number of stacked transformations. Therefore, WASM-MUTATE as a software diversification tool, is a preemptive solution to potential attacks.
